Unexplained Gaps and Oaxaca-Blinder Decompositions

Todd E. Elder, John H. Goddeeris, and Steven J. Haider

April 2009

Abstract

We analyze four methods to measure unexplained gaps in mean outcomes: three decompositions based on the seminal work of Oaxaca (1973) and Blinder (1973) and an approach involving a seemingly naïve regression that includes a group indicator variable. Our analysis yields two principal findings. We show that the coefficient on a group indicator variable from an OLS regression is an attractive approach for obtaining a single measure of the unexplained gap. We also show that a commonly-used pooling decomposition systematically overstates the contribution of observable characteristics to mean outcome differences when compared to OLS regression, therefore understating unexplained differences. We then provide three empirical examples that explore the practical importance of our analytic results.

The authors thank Jeff Biddle, Marianne Bitler, Jonah Gelbach, Kevin Hallock, David Neumark, Mathias Sinning, Gary Solon, Mel Stephens, and Steve Woodbury for very useful comments on an initial draft. All errors remain our own, of course. Haider gratefully acknowledges the financial support of the Australian National University as a Gruen Fellow.
1. Introduction

When faced with a gap in mean outcomes between two groups, researchers frequently examine how much of the gap can be explained by differences in observable characteristics. A common approach to distinguishing between explained and unexplained components follows the seminal papers of Oaxaca (1973) and Blinder (1973), with the original “Oaxaca-Blinder” (O-B) decomposition based on separate linear regressions for the two groups. Letting $d$ be an indicator variable for group membership, $y^d$ be the scalar outcome of interest for a member of group $d$, $X^d$ be a row vector of observable characteristics (including a constant), $\beta^d$ be the column vector of coefficients from a linear regression of $y^d$ on $X^d$, and overbars denote means, it is straightforward to show that

\[
(y^1 - \bar{y}) = (\bar{X} - \bar{X}^0)\hat{\beta}^1 + \bar{X}^0(\hat{\beta}^1 - \hat{\beta}^0).
\]

In this expression, the first and second terms on the right hand side represent the explained and unexplained components of the difference in mean outcomes, respectively.

Both seminal articles pointed out that the decomposition in (1) is not unique in that an equally compelling alternative decomposition exists:

\[
(y^1 - \bar{y}) = (\bar{X} - \bar{X}^0)\hat{\beta}^0 + \bar{X}^1(\hat{\beta}^1 - \hat{\beta}^0).
\]

While the first term on the right hand side of (2) is still interpreted as the explained component, this alternative calculation generally will yield different values from (1), and there is often little reason to prefer one to the other. Many papers acknowledge this ambiguity by simply reporting both decompositions.
Several papers have proposed alternative O-B decompositions, with perhaps the most widely adopted alternative proposed by Neumark (1988).\(^1\) That paper develops a decomposition based on a pooled regression without group-specific intercepts. It is important to emphasize that Neumark (1988) does not analyze the measurement issue of whether his pooled decomposition or those based on (1) and (2) distinguish between explained and unexplained gaps. Rather, he analyzes what fraction of an unexplained wage gap, already purged of productivity differences, represents discrimination, demonstrating that different assumptions regarding employer behavior can lead to each of the three decompositions.\(^2\) Despite this difference in motivation, the pooled decomposition he proposed has been adopted as the primary approach to measuring explained and unexplained gaps in a number of empirical studies.\(^3\)

Researchers also routinely use an even simpler approach to measure unexplained gaps. They estimate the pooled regression including an indicator variable for group membership as well as the other observable characteristics, interpreting the coefficient on the group indicator as the unexplained component. For example, this method has been applied to the measurement of union wage premiums (e.g., Lewis 1986), racial test score gaps (e.g., Fryer and Levitt 2004), and racial wage gaps (e.g., Neal and Johnson 1996).

In this paper, we compare these various methods for assessing the unexplained gap in mean outcomes between two groups. Our analysis yields two principal findings. First, we show that the coefficient on the group indicator from a pooled OLS regression is an attractive approach for

---

\(^1\) Other alternatives in the spirit of Oaxaca (1973) and Blinder (1973) have been put forward by Reimers (1983) and Cotton (1988), who both propose decompositions which are convex linear combinations of those given in (1) and (2). Oaxaca and Ransom (1994) provide an integrative treatment of the various methods.

\(^2\) Neumark (1988) shows how different assumptions regarding employer preferences lead to different estimates of the wage structure that would prevail in the absence of discrimination, and therefore different estimates of discrimination. His analysis starts from the assumption that the set of observable characteristics is sufficiently rich to remove all productivity differences between the groups of interest, so that any unexplained differences represent discrimination or favoritism. We suspect that few researchers interested in decomposing group differences into explained and unexplained components intend to make such an assumption.

obtaining a single measure of the unexplained gap. Second, we show that the pooled O-B strategy systematically overstates the role of observables in explaining mean outcome as compared to OLS with a group indicator, thereby understating unexplained differences. The intuition for this result is straightforward: the pooled regression coefficients on observable covariates are biased due to the omission of group-specific intercepts, which in turn causes the role of observables to be overstated. We then provide three empirical examples that explore the practical importance of our analytic results, two based on wage gaps and one based on test score gaps.

2. The Relationship among Four Measures of the Unexplained Gap

As in the introduction, let $y$ be the scalar outcome of interest, $d$ be an indicator variable equal to 1 for an individual in group 1 and 0 otherwise, $X$ be the vector of observable characteristics (including a constant but not $d$), and overbars denote means. We study four different measures of the unexplained gap in $\bar{y}$ between groups 0 and 1. The first two measures come from the standard O-B decompositions listed in equations (1) and (2): define $\text{Gap}^1$ to be $\bar{X}^0(\hat{\beta}^1 - \hat{\beta}^0)$, the final term in (1), and similarly define $\text{Gap}^0$ to be the final term in (2). The third measure, $\text{Gap}^p$, is the unexplained component from Neumark’s (1988) proposed decomposition,

$$\text{(3)} \quad \bar{y}^1 - \bar{y}^0 = (\bar{X}^1 - \bar{X}^0)\hat{\beta}^p + \bar{X}^1(\hat{\beta}^1 - \hat{\beta}^p) + \bar{X}^0(\hat{\beta}^p - \hat{\beta}^0),$$

where $\hat{\beta}^p$ is defined to be the coefficient vector from the pooled regression of $y$ on $X$. The first term on the right hand side of (3) is again interpreted as the explained component, and the sum of the final two terms is the unexplained component, $\text{Gap}^p$. If $y$ denotes a wage, for example, then these two terms correspond to each group’s advantage or disadvantage relative to the pooled

---

4 Fortin (2006) and Jann (2008) discuss the same potential problem with the pooled O-B decomposition without a group indicator. Both studies mention the omitted variables bias intuition for why excluding the group indicator could be problematic, and both studies propose a solution that is identical to OLS with a group indicator variable. However, neither study develops general expressions for how the four unexplained gaps are related.
wage structure. Finally, the fourth unexplained gap measure, $\text{Gap}^{\text{OLS}}$, is the coefficient on $d$ from the pooled OLS regression of $y$ on $d$ and $X$. We compare these gaps by specifying a population data generating process and then deriving what each of the gaps measure.

2.1. The Case in Which Coefficients Are Equal across Groups

We begin by assuming that the mean outcomes between groups 0 and 1 differ only by a constant and that the outcome is influenced by only one observable characteristic $x$. These assumptions simplify the exposition substantially, but as we describe below, all of the results in this section extend to the case in which the outcome depends on a vector of characteristics $X$. We relax the assumption of equal coefficients across groups in the next subsection.

Specifically, suppose the population relationship between $y$, $d$, and $x$ is

$$y = \delta_0 + \delta_d d + \delta_x x + \varepsilon,$$

with $\varepsilon$ orthogonal to $d$ and to $x$ conditional on $d$.$^5$ Under these strong assumptions, a sensible definition of the population unexplained gap is $\delta_d$. Moreover, under these assumptions, the probability limit of $\text{Gap}^{\text{OLS}}$ is $\delta_d$.

To derive probability limits of the other estimates of the unexplained gap, we introduce some additional notation. An O-B unexplained gap can always be written as the difference in overall mean outcomes minus the difference in predicted mean outcomes, and both of these differences can be denoted by linear projections. Letting $b(z \mid w)$ denote the slope from a linear projection of $z$ on $w$ and a constant, a general expression for an O-B unexplained gap is

$$\text{Gap} = [\bar{y}_1 - \bar{y}_0] - [\hat{\theta}(\bar{x}_1 - \bar{x}_0)]$$

$$= b(y \mid d) - b(\hat{\theta} x \mid d),$$

$^5$ In regressions with the scalar $x$, the constant will be denoted separately, while in the more general case $X$ will denote a vector of characteristics including a constant.
where \( \hat{\theta} \) is a coefficient computed from sample data. The choice of \( \hat{\theta} \) is what distinguishes different O-B decompositions from each other. For example, Gap1 is obtained when \( \hat{\theta} \) is the OLS slope coefficient from a regression of \( y \) on \( x \) and a constant using data from group 1, while Gap\(^0\) is obtained when \( \hat{\theta} \) is the OLS slope coefficient using data from group 0.

Consider the probability limit of an O-B gap under the data generating process described by (4):

\[
\text{plim Gap} = \text{plim } b(y \mid d) - b(\hat{\theta} x \mid d) = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \text{plim} \hat{\theta}
\]

(6)

\[
= \frac{\text{cov}(d, \delta_0 + \delta_x d + \delta_x x + \varepsilon)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \text{plim} \hat{\theta}
\]

\[
= \delta_d + \frac{\text{cov}(d, x)}{\text{var}(d)} \delta_x - \frac{\text{cov}(d, x)}{\text{var}(d)} \text{plim} \hat{\theta}.
\]

Thus, the estimated gap converges to \( \delta_d \) whenever \( \text{plim} \hat{\theta} = \delta_x \). Because \( \text{plim} \hat{\theta} = \delta_x \) in both group-specific regressions, the probability limits of Gap\(^0\) and Gap\(^1\) are \( \delta_d \), implying that Gap\(^0\), Gap\(^1\), and Gap\(^\text{OLS}\) are asymptotically equivalent.

In contrast, Gap\(^p\) generally will not converge to \( \delta_d \). The difference arises because, in a pooled regression that does not include the group-specific intercept \( d \), \( \text{plim} \hat{\theta} \) typically does not equal \( \delta_x \) due to omitted variables bias. To see this formally, consider the probability limit of Gap\(^p\).
\[ \text{plim Gap}^P = \text{plim } b(y \mid d) - b(xb(y \mid x) \mid d) = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, [x \text{cov}(x, y) / \text{var}(x)])}{\text{var}(d)} \]

\[ = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x) \cdot \text{cov}(x, y)}{\text{var}(d) \cdot \text{var}(x)} \]

\[ = \frac{1}{\text{var}(d)} \left( \text{cov}(d, y) - \frac{\text{cov}(d, x) \cdot \text{cov}(x, y)}{\text{var}(y)} \right) . \]

It is useful to compare this expression to an alternative representation of the probability limit of \( \text{Gap}^{\text{OLS}} \). Defining \( \tilde{z}(w) \) to be the component of \( z \) that is orthogonal to \( w \) in the population (so that \( \tilde{z}(w) = z - wb(z \mid w) \)), then

\[ \text{plim Gap}^{\text{OLS}} = \text{plim} \tilde{\delta}_d \]

\[ = \frac{\text{cov}(\tilde{d}(x), \tilde{y}(x))}{\text{var}(\tilde{d}(x))} \]

\[ = \frac{\text{cov}(d, \tilde{y}(x))}{\text{var}(\tilde{d}(x))} - \frac{\text{cov}(x, \tilde{y}(x)) \cdot \text{cov}(d, x)}{\text{var}(\tilde{d}(x)) \cdot \text{var}(x)} \]

\[ = \frac{\text{cov}(d, \tilde{y}(x))}{\text{var}(\tilde{d}(x))} \]

\[ = \frac{1}{\text{var}(\tilde{d}(x))} \left( \text{cov}(d, y) - \frac{\text{cov}(d, x) \cdot \text{cov}(x, y)}{\text{var}(y)} \right) , \]

where the fourth equality follows because \( \text{cov}(x, \tilde{y}(x)) = 0 \) by the definition of \( \tilde{y}(x) \).

Comparing (7) and (8),

\[ (9) \quad \text{plim Gap}^P = \frac{\text{var}(\tilde{d}(x))}{\text{var}(d)} - \text{plim Gap}^{\text{OLS}} . \]

The ratio of the two gaps, \( \frac{\text{var}(\tilde{d}(x))}{\text{var}(d)} \), equals the probability limit of \((1 - R^2)\) from the auxiliary regression of \( d \) on \( x \), so the gaps are equivalent only when \( d \) is orthogonal to \( x \) (in which case observed characteristics explain none of the between-group differences in outcomes). In all
other cases, the probability limit of $\text{Gap}^p$ is smaller than the probability limit of $\text{Gap}^{\text{OLS}}$, which we have shown to be equivalent to $\delta_x$ and the probability limits of $\text{Gap}^0$ and $\text{Gap}^1$.

The intuition for this result is straightforward. The omission of $d$ from a pooled regression leads to omitted variables bias in the estimated coefficient on $x$. Because the coefficient on $x$ captures both the direct effect of $x$ on $y$ and the effect of $d$ on $y$ indirectly through the correlation between $d$ and $x$, it tends to explain “too much” of the gap in outcomes, leading the unexplained gap to be too small. We illustrate this effect in Figure 1 for the case in which $\bar{x} > \bar{x}_0$, $\bar{y}_1 > \bar{y}_0$, and $\delta_x > 0$. The total gap in mean outcomes is $\bar{y}_1 - \bar{y}_0$, and based on the group 1 regression line (the top line in the figure), the explained gap is $\bar{y}_1 - A$ and the unexplained gap is $A - \bar{y}_0$. Note that the steepness of the line determines the magnitudes of the explained and unexplained gaps, so $\text{Gap}^1$ and $\text{Gap}^0$ are identical because the group 1 and group 0 lines are parallel. In contrast, the regression line for the pooled regression (denoted as the dashed line in the Figure) must be steeper than either group line due to omitted variables bias. As a result, $\text{Gap}^p$ must be less than the other three unexplained gap measures.  

Finally, in Appendix A1 we show that the asymptotic relationship given in (9) is also an exact result that holds in finite samples. Further, although we have assumed $x$ is a scalar for notational convenience, the relationship between $\text{Gap}^p$ and $\text{Gap}^{\text{OLS}}$ holds when $x$ is vector-valued and regardless of whether model (4) is correct: in all circumstances, $\text{Gap}^p$ is exactly equal to $\text{Gap}^{\text{OLS}}$ multiplied by $(1-R^2)$ from the auxiliary regression of $d$ on all observable covariates.  

---

6 Neumark (1988), p. 293, makes a similar point about the case illustrated in Figure 1. We note, however, that our finding that $\text{Gap}^p$ is smaller in absolute value than $\text{Gap}^{\text{OLS}}$ does not require that $\bar{x}_1 > \bar{x}_0$, or that either measure is bounded between zero and the overall difference in mean outcomes.

7 An implication of these results is that, while $\text{Gap}^{\text{OLS}}$ and $\text{Gap}^p$ will always have the same sign, the sign of the explained component can differ depending on which approach is used. If $\bar{y}_1 > \bar{y}_0$, $\bar{x}_1 < \bar{x}_0$, and $\delta_x > 0$, then $\bar{y}_1 - \bar{y}_0$ will be smaller than $\text{Gap}^{\text{OLS}}$ and the associated explained component will be negative. In this situation,
2.2. The Case in Which Coefficients Vary across Groups

The relationship between Gap\(^p\) and Gap\(^{OLS}\) presented above is exact and general (see Appendix A1). Thus, in the varying coefficients case, Gap\(^p\) is still systematically less than Gap\(^{OLS}\) whenever the averages of observable characteristics differ between the two groups.

Turning to the relationship between Gap\(^{OLS}\), Gap\(^1\) and Gap\(^0\), we once again begin by assuming that the outcome is influenced by only one observable characteristic \(x\). However, the exact bounding result we obtain for this simple case does not extend to the case when the outcome depends on a vector of characteristics \(X\). We return to this issue below.

Assume again that \(x\) is a scalar and that \(\varepsilon\) is orthogonal to \(d\) and to \(x\) conditional on \(d\), but now we allow the coefficient on \(x\) to vary between the two groups,

\[
(4a) \quad y = \lambda_0 + \lambda_d d + \lambda_x x + \lambda_{dx} dx + \varepsilon .
\]

Equation (6) showed that the probability limit for an O-B unexplained gap based on \(\hat{\theta}\) can be written as

\[
(10) \quad \text{plim} \text{ Gap} = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \text{plim} \hat{\theta} .
\]

Based on this expression, it is straightforward to see that

\[
(11) \quad \text{plim} \text{ Gap}^1 = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \frac{\text{cov}(x, y \mid d = 1)}{\text{var}(x \mid d = 1)}
\]

and

\[
(12) \quad \text{plim} \text{ Gap}^0 = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \frac{\text{cov}(x, y \mid d = 0)}{\text{var}(x \mid d = 0)} .
\]

As we show in the Appendix, Gap\(^{OLS}\) is a weighted average of Gap\(^1\) and Gap\(^0\),

\[
\bar{y}_1 - \bar{y}_0 \text{ may be larger than Gap}^{OLS} \text{ multiplied by } (1 - R^2) \text{ from the auxiliary regression of } d \text{ on } x. \text{ If so, } \bar{y}_1 - \bar{y}_0 \text{ will be larger than Gap}^p, \text{ so that the explained component will be positive. The use of Gap}^p \text{ would therefore imply that observable characteristics explain a positive fraction of an outcome gap, despite the fact that the group with “better” outcomes has “worse” observable characteristics.}
\[(13) \text{Gap}^{\text{OLS}} = \hat{w}^1 \text{Gap}^1 + \hat{w}^0 \text{Gap}^0,\]

with the weights given by sample analogs of the following:

\[(14a) w^1 \equiv \text{plim} \hat{w}^1 = \frac{\Pr(d = 1) \var(x | d = 1)}{\Pr(d = 1) \var(x | d = 1) + \Pr(d = 0) \var(x | d = 0)} \]

\[(14b) w^0 \equiv \text{plim} \hat{w}^0 = \frac{\Pr(d = 0) \var(x | d = 0)}{\Pr(d = 1) \var(x | d = 1) + \Pr(d = 0) \var(x | d = 0)}.\]

It is straightforward to show that these weights are bounded by 0 and 1, implying that \text{Gap}^{\text{OLS}} is always bounded by \text{Gap}^1 and \text{Gap}^0. In addition, the structure of these weights is intuitively appealing, with \text{Gap}^{\text{OLS}} approaching \text{Gap}^1 for large values of \var(x | d = 1) / \var(x | d = 0) and for values of \Pr(d = 1) close to 1. When \var(x) does not vary across groups, the weights are the sample analogues of \Pr(d = 1) and \Pr(d = 0), so that \text{Gap}^{\text{OLS}} is simply the group-size weighted average of \text{Gap}^1 and \text{Gap}^0.

Because \text{Gap}^{\text{OLS}} is a linear combination of \text{Gap}^1 and \text{Gap}^0, OLS itself can be regarded as an O-B decomposition. Specifically, Oaxaca and Ransom (1994) show that the various O-B decompositions that had been proposed take the form of equation (3) above, with $\hat{\beta}^P$ replaced by a general reference vector $\beta^* = \Omega \hat{\beta}^0 + (I - \Omega) \hat{\beta}^1$. The differences between the various decompositions rest with the selection of the weighting matrix $\Omega$. In this notation, the O-B decomposition that corresponds to OLS uses the weighting matrix

\[(15) \Omega^{\text{OLS}} = \text{diag}(\hat{\beta}^{\text{OLS}} - \hat{\beta}^1)(\text{diag}(\hat{\beta}^1 - \hat{\beta}^0))^{-1},\]

where $\text{diag}(\cdot)$ denotes the operator that transforms a vector into a diagonal matrix with zeroes as the off-diagonal elements and $\hat{\beta}^{\text{OLS}}$ is the slope coefficient on $X$ from a pooled regression of $y$ on
$X$ and $d$. In fact, $\text{Gap}^{\text{OLS}}$ is equivalent to the O-B decomposition proposed by Cotton (1988) when $\text{var}(x)$ is constant across groups.

It is important to note that the relationships between $\text{Gap}^{\text{OLS}}$, $\text{Gap}^1$ and $\text{Gap}^0$ are not easily extended to the case when an outcome depends on a vector of characteristics $X$. In particular, just as with the single regressor case described above, $\text{Gap}^{\text{OLS}}$ is still a weighted average of $\text{Gap}^1$ and $\text{Gap}^0$, with weights that are related to the relative group sample size and variance of observables. This result is clear from the general weighting matrix in (15) because these factors will determine the magnitude of $\hat{\beta}^{\text{OLS}}$ relative to $\hat{\beta}^0$ and $\hat{\beta}^1$. However, $\text{Gap}^{\text{OLS}}$ is not necessarily bounded by $\text{Gap}^1$ and $\text{Gap}^0$ when there is more than one observable. Our empirical results in the next section will demonstrate the extent to which $\text{Gap}^{\text{OLS}}$ deviates from $\text{Gap}^1$ and $\text{Gap}^0$ in three different contexts, as well as the extent to which $\text{Gap}^p$ deviates from $\text{Gap}^{\text{OLS}}$.

3. Empirical Examples

We demonstrate the practical importance of the analytic results shown above by presenting three empirical examples: the male-female wage gap among full-time, full-year workers using Current Population Survey (CPS) data; the white-black wage gap among full-time, full-year working males using CPS data; and the white-black test score gap in kindergarten using the fall 1998 assessment of the Early Childhood Longitudinal Study – Kindergarten Cohort (ECLS-K).

---

8 We thank Mathias Sinning for suggesting this notation. Sinning (2009) expands on this idea to develop an O-B decomposition framework for quantile regression.

9 An alternative representation of the weights in equation 13 is $\tilde{w}^1 = \frac{(r - \bar{X}^1)\hat{\beta}_{Xd}}{(\bar{X}^0 - \bar{X}^1)\hat{\beta}_{Xd}}$ and $\tilde{w}^0 = 1 - \tilde{w}^1$ where $\hat{\beta}_{Xd}$ denotes a vector of coefficients on interactions $X \times d$ from a pooled OLS regression of $y$ on $X$, $d$, and the interactions, and $r$ is a vector of coefficients on $d$ from auxiliary regressions of the $X \times d$ interactions on $X$ and $d$. In the scalar $x$ case, $\hat{\beta}_{Xd}$ is also a scalar so it cancels out of this expression, and the resulting expression can be shown to lead to (14a). More generally, however, $\tilde{w}^1$ is not bounded between 0 and 1 because of the presence of the $\hat{\beta}_{Xd}$ terms.
For the first two outcomes we first show results for 1985 and 2001, and for the last we present separate results for reading and math test scores.

For both sets of wage gap results, we use a relatively sparse set of regressors, controlling for age, education, and occupation. We define full-time, full-year workers as those who are at least 18 years old and are working more than 30 hours a week and 40 weeks a year. The hourly wage is measured as annual earnings divided by annual hours, and all models examine the gap in the log hourly wage. For the male-female results, we include all men (group 1) and women (group 0) and control for whether an individual is black. For the white-black results, we only include males who report being black (group 0) or white (group 1). In analyzing white-black test score differentials, we follow the specifications of Fryer and Levitt (2004), who show that seven covariates are sufficient to explain the entire gap in kindergarten test scores between whites and blacks based on GapOLS.

We provide the results in Table 1. For each example, we list the sample size, the total gap between the two groups, the four measures of unexplained gaps discussed in the previous section (Gap1, Gap0, GapP, and GapOLS), and the R² from the auxiliary regression of group status on the other regressors.

These examples illustrate several of the analytic results discussed in the previous section. First, the two standard O-B decompositions can yield dissimilar estimates. Although the results are reasonably similar for the male-female and white-black wage gaps, they lead to noticeably different conclusions for the white-black test score gaps. In particular, Gap1 (using regression

---

10 We include a quartic in age, 4 education categories (less than high school, high school, some college, completed college), and 14 occupation categories (the complete “Major Occupation” codes listed in the CPS for these years).

11 Specifically, we include indicators for whether the mother’s age at first birth was over 30 or less than 20, an indicator for whether the mother received WIC payments, a quadratic in the number of books in the home, the child’s birthweight in ounces, and an NCES-created summary measure of the family’s SES. See Fryer and Levitt (2004) for more details on these measures, and see Appendix Tables 1 and 2 for summary statistics for the estimation samples we use.
coefficients from the white sample) suggests that only 2.5 percent (0.380 / 14.660) of the racial gap in math scores remains unexplained after controlling for this small set of covariates, but nearly 28 percent (4.103 / 14.660) of the math gap is unexplained based on \( \text{Gap}^0 \).

Second, \( \text{Gap}^{\text{OLS}} \) usually lies between \( \text{Gap}^1 \) and \( \text{Gap}^0 \), but not always; \( \text{Gap}^{\text{OLS}} \) is outside of the bounds for the white-black wage gap in 1985. In addition, \( \text{Gap}^{\text{OLS}} \) tends to be closer to the bound corresponding to the group that represents a larger fraction of the data. For all four white-black gaps, \( \text{Gap}^{\text{OLS}} \) is very close to the estimate evaluated at the white coefficients (\( \text{Gap}^1 \)), but it is approximately in the middle of \( \text{Gap}^1 \) and \( \text{Gap}^0 \) for the male-female wage differential, consistent with the roughly equal shares of males and females in the population.

Third, the deviation between \( \text{Gap}^p \) and \( \text{Gap}^{\text{OLS}} \) is exactly related to the \( R^2 \) from the auxiliary regression of the group indicator on the other explanatory variables (\( \text{Gap}^p = (1-R^2) \times \text{Gap}^{\text{OLS}} \)). \( \text{Gap}^p \) still falls between \( \text{Gap}^1 \) and \( \text{Gap}^0 \) in three cases (in the white-black wage differential in 1985 and both test score differences), but in the other three it does not. \( \text{Gap}^p \) is substantially outside the \( \text{Gap}^1 \) and \( \text{Gap}^0 \) estimates for both male-female wage gaps because of the high \( R^2 \) of the auxiliary regression and the associated attenuation of \( \text{Gap}^p \) relative to \( \text{Gap}^{\text{OLS}} \).\(^{12}\)

As further illustration of the relationships among the four \( \text{Gap} \) measures, Figures 2 and 3 show the white-black and male-female wage gaps for each year between 1985 and 2007. In the male-female case shown in Figure 2, the plots of \( \text{Gap}^{\text{OLS}}, \text{Gap}^1, \) and \( \text{Gap}^0 \) are quite similar. \( \text{Gap}^p \) is substantially lower in all years, due to the relatively high power of the covariates in explaining group membership, i.e., men and women are substantially different on observable dimensions. In the white-black case shown in Figure 3, \( \text{Gap}^0 \) is consistently larger than \( \text{Gap}^1 \), but the plots of \( \text{Gap}^{\text{OLS}} \) and \( \text{Gap}^p \) are essentially identical to \( \text{Gap}^1 \) because the white group represents a large fraction of the population and because the explanatory variables do not predict group

\(^{12}\) Oaxaca and Ransom (1994) found a similar result in their male-female wage example (see their Table 3, column 2), but they did not comment that this result was to be expected.
membership. In both graphs, $\text{Gap}^{\text{OLS}}$ lies in between or nearly in between $\text{Gap}^1$ and $\text{Gap}^0$ for every year.

4. Discussion and conclusion

We analyze four methods to measure unexplained gaps in mean outcomes, three based on the decomposition methods of Oaxaca (1973) and Blinder (1973) and one based on a pooled regression with a group indicator variable. Our analysis yields two principal findings. We show that, in the case of a single observable characteristic, the coefficient on the group indicator from a pooled OLS regression is a weighted average of the unexplained gaps from the two standard O-B approaches, with intuitively sensible weights that are bounded between 0 and 1 and sum to 1. The strict bounding result on these weights, however, does not extend to the case when there is more than one regressor. Thus, although the unexplained gap from a pooled OLS regression reflects the overall relationship between the observable characteristics and the outcome variable, this unexplained gap is no longer strictly bounded by the two standard O-B gaps. In contrast, we show that the O-B pooling strategy without a group indicator systematically overstates the contribution of observables to mean outcome differences, therefore understating unexplained differences. Thus, in circumstances where the decompositions are used to separate between explained and unexplained gaps, the O-B pooling strategy systematically fails to do so.

To explore the practical significance of our results, we provide empirical examples involving white-black and male-female wage differentials and the white-black kindergarten test score gap. These examples demonstrate that $\text{Gap}^{\text{OLS}}$ is typically close to the standard Oaxaca-Blinder unexplained gaps but systematically larger than $\text{Gap}^p$. $\text{Gap}^p$ will deviate from $\text{Gap}^{\text{OLS}}$ to the extent that there are differences in the means of observable characteristics between the two groups. This deviation can be large enough to drive $\text{Gap}^p$ substantially below both standard O-B measures, as is the case with the male-female wage differentials.
Taken together, our analytical and empirical results suggest that the pooling O-B decomposition without a group-specific indicator should not be used to distinguish between explained and unexplained gaps, although this method may be useful to assess how much of an unexplained gap represents discrimination if specific assumptions are met. In contrast, Gap$^{\text{OLS}}$ provides an attractive summary approach to separate between-group mean differences into explained and unexplained components.
Appendix

A1. The exact relationship between Gap$^{\text{OLS}}$ and Gap$^{P}$

Consider a sample of observations on $y$, a scalar outcome of interest, $d$, an indicator variable for group membership, and $X$, a vector of observed characteristics. For this appendix section define each to be the vector or matrix of deviations from its respective sample mean. Further, define $P = X(X'X)^{-1}X'$ to be the projection matrix onto $X$ and $M = I - P$ to be its complement. Note that we need make no assumptions about relationships in the population.

Gap$^{\text{OLS}}$ is then given by

(A1) \[ \text{Gap}^{\text{OLS}} = (d'Md)^{-1}(d'My). \]

Similar to equation (7) in the text, Gap$^{P}$ can be expressed as the difference of two regression coefficients, one that equals the total gap between the two groups and one that equals the predicted gap, which is constructed using fitted values from a pooled regression of $y$ on $X$.

Therefore,

(A2) \[
\begin{align*}
\text{Gap}^{P} &= (d'd)^{-1}d'y - (d'd)^{-1}d'Py \\
&= (d'd)^{-1}d'My \\
&= (d'd)^{-1}(d'Md) \times \text{Gap}^{\text{OLS}} \\
&= (1 - R_{d,X}^2) \times \text{Gap}^{\text{OLS}},
\end{align*}
\]

where $R_{d,X}^2$ is the $R^2$ from the auxiliary regression of $d$ on $X$. As a result, Gap$^{P}$ will always be smaller than Gap$^{\text{OLS}}$ except when $d$ is orthogonal to $X$, which corresponds to the case in which covariates can explain none of the difference across groups in average outcomes.

A2. The relationship between Gap$^0$, Gap$^1$, and Gap$^{\text{OLS}}$ in the scalar $x$ case

We first derive two expressions that will be useful in the final result. Defining $\pi = \text{Pr}(d = 1)$, note that
\[ \text{var}(x) = (1 - \pi) \times \left[ \text{var}(x \mid d = 0) + [E(x \mid d = 0) - E(x)]^2 \right] + \pi \times \left[ \text{var}(x \mid d = 1) + [E(x \mid d = 1) - E(x)]^2 \right] \]
\[ = (1 - \pi) \times \left[ \text{var}(x \mid d = 0) + [E(x \mid d = 1) - E(x \mid d = 0)]^2 \pi^2 \right] + \pi \times \left[ \text{var}(x \mid d = 1) + [E(x \mid d = 1) - E(x \mid d = 0)]^2 \right] (1 - \pi)^2 \]
\[ = (1 - \pi) \times \text{var}(x \mid d = 0) + \pi \times \text{var}(x \mid d = 1) + \frac{\text{cov}(x, d)^2}{\text{var}(d)^2} \times \left[ (1 - \pi)\pi^2 + \pi(1 - \pi)^2 \right] \]
\[ = (1 - \pi) \times \text{var}(x \mid d = 0) + \pi \times \text{var}(x \mid d = 1) + \frac{\text{cov}(x, d)^2}{\text{var}(d)} \times \left[ \pi \text{var}(d) + (1 - \pi) \text{var}(d) \right] \]
\[ = (1 - \pi) \times \text{var}(x \mid d = 0) + \pi \times \text{var}(x \mid d = 1) + \frac{\text{cov}(x, d)^2}{\text{var}(d)} \times \left[ \pi \text{var}(d) + (1 - \pi) \text{var}(d) \right] \]

The first equality is the decomposition of the variance of \( x \) into “within group” and “between group” components, the second equality follows from applying the law of iterated expectations to \( E(x) \), the third follows because \( E(x \mid d = 1) - E(x \mid d = 0) = \text{cov}(x, d) / \text{var}(d) \) for any binary variable \( d \), and the fourth because \( \text{var}(d) = \pi(1 - \pi) \) for any binary variable \( d \). Similar logic implies that

\[ \text{cov}(x, y) = (1 - \pi) \times \text{cov}(x, y \mid d = 0) + \pi \times \text{cov}(x, y \mid d = 1) + \frac{\text{cov}(d, x) \text{cov}(d, y)}{\text{var}(d)}. \]

Beginning with the result in (13), we combine (11), (12), (14a), and (14b):

\[ \text{plim} \left[ \hat{\omega}^1 \text{Gap}^1 + \hat{\omega}^0 \text{Gap}^0 \right] = w^1 \left[ \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \frac{\text{cov}(x, y \mid d = 1)}{\text{var}(x \mid d = 1)} \right] \]
\[ + w^0 \left[ \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \frac{\text{cov}(x, y \mid d = 0)}{\text{var}(x \mid d = 0)} \right] \]
\[ = \frac{\text{cov}(d, y)}{\text{var}(d)} - \frac{\text{cov}(d, x)}{\text{var}(d)} \Pi, \]

where

\[ \Pi = \frac{\pi \times \text{var}(x \mid d = 1)}{(1 - \pi) \times \text{var}(x \mid d = 0)} \frac{\text{cov}(x, y \mid d = 1) \text{var}(x \mid d = 1)}{(1 - \pi) \times \text{var}(x \mid d = 0) \text{cov}(x, y \mid d = 0) \times \text{var}(x \mid d = 0) \times \text{var}(x \mid d = 0)} \]

Simplifying \( \Pi \),
\[
\Pi = \frac{\pi \times \text{var}(x \mid d = 1) \text{cov}(x, y \mid d = 1)}{\pi \times \text{var}(x \mid d = 1) + (1 - \pi) \times \text{var}(x \mid d = 0)} + \frac{\text{cov}(x, y \mid d = 0)}{\text{var}(x \mid d = 1) + (1 - \pi) \times \text{var}(x \mid d = 0)}
\]

\[
(A6) = \frac{\pi \times \text{cov}(x, y \mid d = 1) + (1 - \pi) \times \text{cov}(x, y \mid d = 0)}{\pi \times \text{var}(x \mid d = 1) + (1 - \pi) \times \text{var}(x \mid d = 0)}
\]

\[
\text{cov}(x, y) = \frac{\text{cov}(d, x) \text{cov}(d, y)}{\text{var}(d)}
\]

\[
\text{var}(x) = \frac{\text{cov}(d, x)^2}{\text{var}(d)}.
\]

The equality on the last line follows from using (A3) and (A4) to simplify the preceding line. As a result,

\[
\text{plim} \left[ \hat{\omega}^i \text{Gap}^i + \hat{\omega}^0 \text{Gap}^0 \right] = \frac{\text{cov}(d, y)}{\text{var}(d)} \left[ \frac{\text{cov}(x, y) - \frac{\text{cov}(d, x) \text{cov}(d, y)}{\text{var}(d)}}{\text{var}(x) - \frac{\text{cov}(d, x)^2}{\text{var}(d)}} \right]
\]

\[
(A7) = \frac{\text{cov}(d, y) \text{var}(x) - \text{cov}(d, x) \text{cov}(x, y)}{\text{var}(x) \text{var}(d) - \text{cov}(d, x)^2}.
\]

Recall from the text that

\[
(A8) \quad \text{plim Gap}^{\text{OLS}} = \frac{1}{\text{var} \left( \hat{d}(x) \right)} \times \left( \frac{\text{cov}(d, y)}{\text{var}(x) - \frac{\text{cov}(d, x) \text{cov}(x, y)}{\text{var}(x)}} \right).
\]

Since \( \hat{d}(x) \) represents the residuals from a population regression of \( d \) on \( x \),

\[
\text{var}(\hat{d}(x)) = \text{var} \left[ d - x \frac{\text{cov}(d, x)}{\text{var}(x)} \right]
\]

\[
(A9) = \text{var}(d) - \frac{\text{cov}(d, x)^2}{\text{var}(x)}.
\]

This implies that (A8) can be rewritten as follows:
\[
\text{plim Gap}^{\text{OLS}} = \frac{1}{\text{var}(d(x))} \times \left( \text{cov}(d, y) - \frac{\text{cov}(d, x) \text{cov}(x, y)}{\text{var}(x)} \right) \\
= \frac{\text{var}(x)}{\text{var}(d) \text{var}(x) - \text{cov}(d, x)^2} \left( \frac{\text{cov}(d, y) \text{var}(x)}{\text{var}(x)} - \frac{\text{cov}(d, x) \text{cov}(x, y)}{\text{var}(x)} \right) \\
= \frac{\text{cov}(d, y) \text{var}(x) - \text{cov}(d, x) \text{cov}(x, y)}{\text{var}(x) \text{var}(d) - \text{cov}(d, x)^2}.
\]

Comparing (A7) and (A10) gives the desired result.
